Seamless Web Data Entry for SAS® Applications
D.J. Penix, Pinnacle Solutions, Indianapolis, IN

ABSTRACT

For organizations that need to implement a robust data entry solution, options are somewhat limited on the SAS® platform. The SAS/FSP® module provides integrated tools for data entry, computation, query, editing, validation, display, and retrieval; however, the solution falls short for organizations that need to deploy a web-entry system on a thin-client platform (i.e. Internet Explorer, Mozilla Firefox, etc.) Some companies will tackle the problem using other technologies such as HTML, .NET, or JAVA. But each of these approaches requires expertise that is often beyond the typical SAS programmer to build and maintain. Built upon an open-source platform, a simple, yet elegant, data entry solution can be obtained. The application data can then be integrated into any SAS application by connecting it via the SAS/ACCESS® modules.

TYPICAL WEB DATA ENTRY FEATURES

Although requirements for a web data entry system may vary from company to company, there are several features that are typically requested. Based on informal discussions with various customers, the following items were at the top of the list:

- 100% thin-client data entry using a browser such as Internet Explorer or Mozilla Firefox.
- Ability to enter data on customized data entry screens that simulate business forms.
- Ability to use color and highlighting to enhance the screen display.
- Ability to validate and cross-validate data automatically or define custom error-checking logic.
- Ability to compute new field values--instantly--based on values entered by the user.
- Ability to browse and edit data in both spreadsheet (horizontal) and column (vertical) form.
- Ability to capture audit trail information.
- Ability to view and edit data from SAS data files or external databases such as Oracle, DB2, Sybase, MS SQL, etc.
- Ability to simplify data entry using selection lists or table look-up. When a user enters information in one field, the web data entry form should automatically pull in information in other fields.
- Easy to maintain without SAS expertise.
- Ability to leverage the back-end data with their SAS environment to produce analytics, reporting, or any other use.

SYSTEM ARCHITECTURE

For some organizations, a data entry solution based on the SAS/FSP¹ software is adequate. This solution does allow organizations to build complex data entry screens that mimic complex business data forms and using the power of SAS database connectivity features, can access almost any warehouse on the back end. However, the solution is limited in that it is a “client” based system (which requires SAS to be installed on a desktop) and it is not easily scalable for large organizations that may have users spread throughout multiple locations. A simple, scalable, web-based solution would be more desirable.

So what architecture and software options are available for organizations looking to get started building web applications? One such option is to look at a bundled solution called LAMP. LAMP is an acronym for a solution stack of free and/or open source software, originally coined from the first letters of Linux (operating system), Apache (HTTP Server), MySQL (database software), and PHP (scripting language), principal components to build a viable general purpose web server.² WAMP is similar, except instead of Linux, it is supported on the Windows operating system. There are other variants as well, such as MAMP (Mac OS), SAMP (Solaris), and OpAMP (OpenBSD).

Although the original authors of these programs did not design them all to work specifically with each other, the development philosophy and tool sets are shared and were developed in close conjunction. The software combination has become popular because it is free of cost, mostly open-source, and therefore easily adaptable.

The stacks are widely used because it offers a great number of advantages for developers. It is easy to code, easy to deploy, you can develop it locally and then push it to the web, and it is available on almost every web host. Even the cheapest web host options

allow you to run PHP and MySQL. And because of the wide range of supported operating systems that are available, you can get started building web applications very quickly for almost any system configuration!

APACHE
The Apache HTTP Server is open-source web server software. It is developed and maintained by an open community of developers under the backing of the Apache Software Foundation. Apache supports a variety of features, many implemented as compiled modules that extend the core functionality. These can range from server-side programming language support to authentication schemes. Some common language interfaces support Perl, Python, Tcl, and PHP.

MySQL
MySQL is a relational database management system (RDBMS) that runs as a server providing multi-user access to a number of databases. Because MySQL is primarily an RDBMS, it does not contain a GUI tool to administer the MySQL databases or manage data contained within. Users may use the included command-line tools, or download various MySQL frontends from 3rd parties that have developed desktop software and web applications to manage MySQL databases, build database structure, and work with data records. One such GUI tool is phpMyAdmin. Written in PHP, it is a free web-based frontend and is included within the LAMP solution stack.

PHP
PHP is a general-purpose scripting language that is especially suited to server-side web development where PHP generally runs on a web server. Any PHP code in a requested file is executed by the PHP runtime, usually to create dynamic web page content. It can also be used for command-line scripting and client-side GUI applications. PHP can be deployed on most web servers, many operating systems and platforms, and can be used with many relational database management systems.

As of April 2007, over 20 million Internet domains had web services hosted on servers with PHP installed and mod_php was recorded as the most popular Apache HTTP Server module.

Getting started with PHP is very easy. The following code snippet shows the necessary code for the classic “Hello World” example. In this case, the PHP code is embedded within a normal HTML tag:

```html
<html>
<head>
<title>My PHP Hello world</title>
</head>
<body>
<?php
  echo "Hello World";
?
</body>
</html>
```

Figure 2 - Hello World PHP Example

The file can then be saved as test.php and made available to a web server. The following is the rendered page.

Figure 3 - Hello World Output

PUTTING IT ALL TOGETHER

Although there are many software platforms that can accelerate web development, this paper explores some of the key concepts that were utilized in building web data entry systems.

The initial process in developing the application is to define the data “metadata” for the PHP code. The metadata consists of the data types, lengths, look-up

value sources, labels, validation rules, etc. When documented in a spreadsheet (or within a web data entry application itself), this process can help facilitate the requirements gathering process.

The following spreadsheet shows an example of collecting metadata items for a sample healthcare questionnaire.

**WEB DATA ENTRY COMPONENTS**

The first component of a data entry system that needs to be defined is security. The PINNACLE COMPASS solution utilizes its own security tables that contain fields such as username, password (encrypted), active/deactivated, group membership, and email. These security tables are simply maintained within the MySQL database; however, it could also be maintained in a separate LDAP database. The COMPASS solution can even be connected to Microsoft Active Directory to allow corporate network credentials to be used. Although not necessarily required within all organizations, the COMPASS solution even supports email reminders for users that forget passwords, as well as provide a built-in mechanism for first-time users to register a request for system access. With this feature, an automated email is sent to an administrator, and then access can be granted or denied by management.

![Figure 6 - User Logon Screen](image)

Once logged into the system, the user is redirected to the primary data entry page.

![Figure 7 - Sample Data Entry Form](image)

There are various components of the page that will allow the user to quickly navigate and work with the data. At the top row of the screen, the following buttons are available:

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Logon</td>
<td>User logon</td>
</tr>
<tr>
<td>User profile</td>
<td>User profile settings</td>
</tr>
<tr>
<td>Saved Searches</td>
<td>Saved searches</td>
</tr>
<tr>
<td>Add page</td>
<td>Add new page</td>
</tr>
<tr>
<td>Edit page</td>
<td>Edit existing page</td>
</tr>
</tbody>
</table>

Some of these high-level actions will be discussed later in this paper, however starting from left to right,
the user can log out, change the password, conduct an advanced search, export the results, print the current page, or print all pages.

Immediately below those buttons are tabs that allow the user to view different components of the example survey or even view custom HTML pages. In this example, there are actually 4 parts to the survey and a custom report at the end.

The default entry screen is displayed in horizontal format (many records in a row-by-row fashion) however the same form can also be displayed in vertical format (single record on one screen).

Each record in the horizontal layout has several quick click icons.

The icon allows the user to edit the field, as displayed in the following screen shot.

The icon allows the user to copy an existing record. For this example, "Response ID" is the key field and is set up as auto-number in the database. It will be automatically assigned in MySQL to ensure uniqueness, however all other fields will automatically be populated with duplicate values.

The icon allows the user to simply browse a record without putting it into edit mode. The default layout is in vertical fashion.

The icon allows the user to select one or more records. Alternatively, by clicking on the select box at the top of the screen, the user can select all records at once. The multiple select record function is useful for performing in-line edits on more than one record at a time. The row of buttons immediately above the data will allow the user to Edit, Delete, Export, or Print the selected records.

After the in-line edit icon is clicked, the changes to display two new icons . These icons allow the user to either save (check mark button) or cancel (undo button) the changes to the data. For that record, the data itself turns into an editable value.
The survey links follow the selection boxes. The following screenshot shows the results of clicking on the "Part 2" link for an individual record.

This function allows the user to see multiple parts of the survey simultaneously, which can be useful for understanding the context of the different data pieces. The user can also immediately proceed to Part 2 of the survey, or by clicking on the red X, can cancel the view and return to normal viewing mode.

Other features of the application include the ability to export the data, either for specifically selected records, or the entire database. Export formats include Excel, Word, CSV, or XML.

The user can also print selected records. Although any complex reporting needs would be better served in SAS, it is a handy feature for doing a quick print for a handful of records.

The COMPASS solution also has some AJAX-based functionality implemented within the PHP making available some useful features such as the ability to search information more easily with the Google-like auto-suggest feature. The web pages with AJAX-driven dependent dropdown boxes are also loaded faster.

There is also an advanced search window that permits users to perform more complex queries.

---

And, the user can even create their custom search criteria in a floating window.

![Undocked Customized Floating Window](image1.png)

**Figure 17** - Undocked Customized Floating Window

Other features of the application include audit-trail logging, sorting the data, and automatic record locking to prevent multiple users from editing the same record simultaneously.

![Record Locking Feature](image2.png)

**Figure 18** - Record Locking Feature

The MySQL database can even support BLOB (Binary Large Object) data types, which are ideal for scanned images such as photographs, case report forms, x-rays, or other relevant documents.

![BLOB Object for Binary File Types](image3.png)

---

**INTEGRATION WITH SAS**

As you now see, a robust web data entry system can be built independently of SAS. By using widely available free software stack such as Apache web server, MySQL, and PHP, you can build complex data entry screens for the web. Once you've collected the data, you can fully take advantage of the reporting and analytics features of SAS.

To surface the data into SAS, you simply need to have the corresponding SAS/ACCESS technology licensed. In this example, one would only need to have SAS/ACCESS Interface to MySQL in order to get access to the data. The screenshot below shows the data being browsed in Enterprise Guide or any other SAS application.

![Accessing MySQL Data in SAS](image4.png)

**Figure 20** - Accessing MySQL Data in SAS

Notice that the raw data and variable names correspond to the variable names defined in the metadata worksheet. The underlying data is all stored as numeric values, even though the users see drop down lists with the business label descriptions that are more intuitive.

![Raw Data Unformatted](image5.png)

**Figure 21** - Raw Data Unformatted

A SAS view can easily be created that applies the labels and formatted values. The following is a screenshot of a SAS view within Enterprise Guide.

---

CONCLUSION

Although there are many approaches available for building data entry forms on the web, they usually involve a high level of programming expertise or lack the robust functionality of a mature system. Using a readily available and free software stack of tools such as Apache, MySQL, and PHP, one can quickly and easily develop sophisticated thin-client data entry solutions. Once the back-end data has been established, SAS can get access to the data using one of the SAS/ACCESS technologies. Alternatively, one could build a data entry solution using the SAS ODBC driver and input the data directly into SAS datasets if a 3rd party database was not preferred.
