Constructing Interoperable Study Documents From A Semantic Technology-based Repository

A Content Management System can capture, store, and exchange documents that are used in business processes. It processes data and information related to the study. The system can manage storage of study documents. It is not necessary to look for the right document, especially if the document is long and contains many themes. Even if the metadata can be envisaged as a cloud of terms, it is not easy to get a computer to understand the significance of a term.

XML should allow a computer to understand the significance of a term. A study Protocol Version is a short-hand way to refer to a given study.

The model can perform logical inference to deduce facts from other facts that have already been deduced. Fact 1 can be specified (e.g. using SPARQL, a query language based on the RDF data model) and fact 2 can be specified (e.g. using SPARQL).
